Abstract

Background

Buprestidae is a group of beetles of important conservation and phytosanitary value that is poorly studied in the Tuscan Archipelago and the limited faunistic knowledge available refers to a few scant historical records.

New information

The present contribution increments the species documented in the Archipelago from 27 to 51, providing more than 300 georeferenced occurrence records, derived from both direct field research and citizen science via iNaturalist. Of particular importance is the discovery of *Eurythyrea quercus* on Isola d'Elba, an uncommon and localised species currently critically endangered.

Keywords

biodiversity, faunistic, Jewel beetles, PNRR, wood borers

Introduction

The Tuscan Archipelago, inclusive of the Tuscan Archipelago National Park and recognised as Man and the Biosphere Reserve by UNESCO, is considered one of the major biodiversity hotspots of the Mediterranean Basin (Mittermeier et al. 2005). This Archipelago, rich in endemisms, Sardinian-Corsican elements and taxa originating from the Italian mainland, presents a rather complex biogeographic history linked to its origin during the convergence between Europe and Africa (Peccerillo 2017), the Pleistocene sea regression and driven by the changes that occurred in more recent times (Miocene to present), including those mediated by humans and their activities (Fattorini 2009, Ruzzier et al. 2021). The area has been the subject of extensive floristic, faunistic, and biogeographic studies in historical and more recent times; however, if we exclude vascular plants (e.g. Arrigoni et al. (2003), Foggi et al. (2014), Lazzaro et al. (2014), Carta et al. (2018)), vertebrates (e.g. Marinis et al. 1996, Angelici et al. 2009, Amori et al. 2015) and some selected groups of invertebrates (e.g. Dapporto and Cini (2007), Ceccolini et al. (2012), Rocchi et al. (2014), Fattorini et al. (2017), Barbato et al. (2018), Bellò and Ruzzier (2019), Ruzzier et al. (2020)), much still remains to be studied and important knowledge gaps exist regarding the richness and diversity of invertebrates on the various islands of the Archipelago. Coleoptera, in particular, represent a huge part of this hidden biodiversity and several families have never been addressed in their entirety. Buprestidae Leach, 1815 (Coleoptera, Buprestoidea) are a rather diverse beetle family counting more than 15,000 described species worldwide (Bellamy 2008), with more than 200 taxa recorded in Italy (Lobl and Lobl 2016). On the Tuscan Archipelago, the group has been poorly investigated, with only twenty-seven species recorded to date (Poggi 1976, Gobbi 1983, Curletti 1994, Curletti 2021). Buprestid beetles, thanks to their biology closely linked to plants, constitute an important element of biodiversity whose conservation is directly dependent on the protection of woodland and meadow environments. Many species are, in fact, included in the Red List of Saproxylic Beetles at both the Italian and European levels, demonstrating their vulnerability to habitat loss, degradation and fragmentation (Nieto and Alexander 2010, Audisio et al. 2014). In addition, several Buprestidae are of phytosanitary relevance (e.g. Evans et al. (2004), Sever et al. (2012), Ohsawa (2017), Jendek et al. (2018)) and interest in them grows with a view to protection and prevention against the introduction of non-native species (Ruzzier et al. 2023). The main objective of this contribution is, therefore, to update the knowledge status of the Buprestidae of the Tuscan Archipelago, providing up-to-date distribution data of the species on the various islands and to highlight, where possible, important elements of value or any critical issue.

Materials and methods

Specimens cited in this paper are deposited in the following collections: LFPC - Leonardo Forbicioni private collection, NatLab Museum, Portoferraio (LI, Italy); MGPC - Maurizio Gigli private collection, Guidonia (Rome, Italy); SNPC - Stefano Nappini private collection, Castiglion della Pescia (GR, Italy); MBPC - Marco Bastianini private collection Gavorrano (GR, Italy); ABPC - Andrea Beltramini private collection, Firenze (FI, Italy). The IUCN Red List categorisation for saproxyllic species used in this manuscript follows that of Audisio et al. (2014). Since there is no unanimous interpretation of the use and validity of *Agrilus* subgenera, we refrain from their use in this paper.

Study area

The Archipelago, located in the northern part of the Tyrrhenian Sea, sits at about halfway between Corsica and the Italian Peninsula and consists of seven main islands (Elba, Giglio, Capraia, Montecristo, Pianosa, Giannutri and Gorgona) and a series of islets and skerries.

Checklist of the Buprestidae of the Tuscan Archipelago

Subfamily Agrilinae

Tribe Agrilini

Agrilus angustulus subsp. *angustulus* (Illiger, 1803)

Discussion

Prior to the present contribution, only 27 species of Buprestidae were reported from the Tuscan Archipelago and mostly on the basis of single or a few scant specimens (Poggi 1976, Gobbi 1983, Curletti 1994). The present research produced 341 occurrence records

(Suppl. material 1); 282 constitute original new records, 49 of which were retrieved from iNaturalist and 233 from collected specimens (430 specimens in total). These observations allowed increasing the species known for the Archipelago from 27 to 51, just slightly under a quarter of all buprestid species in Italy (Figs 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14). All the Buprestidae subfamilies present on the Italian territory have their representatives in the Tuscan Archipelago and *Agrilus* Curtis, 1825 (tribe Agrilini) and *Anthaxia* Eschscholtz, 1829 (tribe Anthaxiini) are the genera most represented, with 13 and 10 species, respectively. The island on which the largest number of species are currently documented is Elba (49), followed by Giglio (10), while the remaining islands of the Archipelago have no or few scattered records (Table 1). The local fauna does not include any strictly endemic taxa, except for two Italian endemics, namely *Agilus etruscus* Curletti, 2013 and *Agilus evocatus* Curletti 2021. Concerning larval trophic biology, according to the categories given in Curletti (1994), the 51 species treated are subdivided as follows: two phytophagous endophyte, five hypogebiont poophagus endophyte, five epigebiont poophagus endophyte, two hypogebiont arboreal xylophagous endophyte, 24 epigebiont arboreal xylophagous endophyte, five hypogebiont arboreal xylophagous endophyte and seven epigebiont arboreal xylophagous endophyte species (Suppl. material 1). The biology of *Agrilus evocatus* Curletti remains still unknown.

Table 1.

Presence of species for each island in the Tuscan Archipelago (alphabetical order).

<i>Trachys troglodytiformis</i>	X					

Of the 51 species recorded, about 60% are included in the Italian Red List of Saproxylic Beetles (Audisio et al. 2014) and specifically 28 taxa fall in the Least Concern (LC) category, one in the Nearly Threatened (NT) and one taxon, *Eurythyrea quercus* (Herbst, 1780), in the Critically Endangered (CR) category. Of particular importance is the discovery of multiple specimens (fresh remains) of *E. quercus* inside trunks of *Castanea sativa* Mill. on the northern slopes of Monte Perone (Isola d'Elba) (Figs 15, 16). This taxon, with a Pontic-Mediterranean distribution, is generally sporadic and localised in continental Europe and very rarely in Italy, where it is known only for a few historical records and a recent discovery in Piedmont (Curletti 1980, Curletti and Casale 2021). This species usually develops on large branches and trunks of centuries-old Fagaceae of the genus *Quercus* (*Q. ilex* L., *Q. petraea* (Matt.) Liebl., *Q. pubescens* Willd., *Q. robur* L. and *Q. suber* L.) and on *Castanea sativa* Mill. (Hellrigl 1978, Bily 2002), as also confirmed by the present findings. Adults fly during summer, where they rest on the leaves of tree canopies. Mating occurs in the upper canopy and oviposition generally occurs in the afternoon (Helclová 2022). Females lay eggs on naked wood of living trees presenting stressed or dead parts due to lightning, frost or wind damage (Zabransky 1991); in addition, the female may select debarked wood previously attacked by *Cerambyx cerdo* (Linnaeus, 1758), *Trichoferus pallidus* (Olivier, 1790) (Cerambycidae) and *Dermestoides sanguinicollis* (Fabricius, 1787) (Cleridae) for oviposition (Bily 2002, Helclová 2022). Larval development takes two years under optimal conditions and the larvae need trees with large diameter trunks or branches (> 50 cm) to maintain the ideal humidity level (Zabransky 1991). Due to these peculiar ecological exigencies and the substrate required for its reproduction, *E. quercus* is considered a first-degree forest relict that has disappeared in most of its potential range and its presence is currently heavily localised and limited to almost pristine biotopes (Zabransky 1991).

Final considerations

This research has further confirmed the importance of the Tuscan Archipelago as a Mediterranean biodiversity hotspot and, in particular, how such a restricted and scattered ecosystem can host almost a quarter of all Italian Buprestidae. Currently, Elba is the island with the highest species richness, a condition influenced by the greater sampling effort, but also by its highly diversified flora, a feature that is substantially reduced in most of the other islands of the Archipelago. Therefore, as research continues, we can certainly expect an increase in the number of taxa on smaller islands despite not being as substantial as recorded for Isola d'Elba. We expect in the next few years to be able to sample the smaller islands more extensively, varying the periods and methods of capture to increase the likelihood of finding species whose presence is expected, but which have, so far, remained elusive. The substantial diversity of species found, 60% of which are included in the Red List of Italian saproxylic beetles, further enhances the Tuscan Archipelago as a national biodiversity repository and an important core for the conservation of localised, rare or declining species. The conservation of these taxa obviously requires appropriate management and conservation plans, especially for private areas and those not included in the Tuscan Archipelago National Park; in fact, for the most endangered species, the existence of key forest elements where wise management is applied is crucial. In addition, although there are no strictly endemic elements, the protection of the local fauna from non-native species or non-native populations is fundamental to the preservation of the Archipelago's specific and genetic heritage. In this regard, better regulation and control of naval traffic and the transduction of wood material, drivers already widely recognised as the main ones for the introduction of non-native and invasive elements, would prevent or at least reduce the risk of introducing potentially harmful taxa to local biodiversity.

Acknowledgements

The authors would like to thank the Tuscan Archipelago National Park for its partnership and constant support of the research activities of World Biodiversity Association. Heartfelt thanks to Francesco Izzillo[†]for providing valuable information on the biology of *E. quercus*, to Maurizio Gigli for the photos of *E. quercus* and *A. marozzinii*, to Emanuele Paggetti for the identification of some of the specimens collected, to the Cocchia family, owners of the "Fonte di Zeno" farmhouse, for allowing the research within the chestnut grove on their property and to all the people who shared data and made it possible to study the materials in their collections. The authors also acknowledge the support of NBFC to the University of Roma Tre, Department of Science and to the University of Milano-Bicocca, Department of Earth and Environmental Sciences, funded by the Italian Ministry of University and Research, PNRR, Missione 4 Componente 2, 'Dalla ricerca all'impresa', Investimento 1.4, Project CN00000033.
