Results of a multi-taxon approach. Biodiversity Data Journal 4: e7057. doi: [10.3897/BDJ.4.e7057](https://doi.org/10.3897/BDJ.4.e7057)

Abstract

Background

Urban green spaces can harbor a considerable species richness of plants and animals. A few studies on single species groups indicate important habitat functions of cemeteries, but this land use type is clearly understudied compared to parks. Such data are important as they (i) illustrate habitat functions of a specific, but ubiquitous urban land-use type and (ii) may serve as a basis for management approaches.

New information

We sampled different groups of plants and animals in the Weißensee Jewish Cemetery in Berlin (WJC) which is one of the largest Jewish cemeteries in Europe. With a total of 608

species of plants and animals, this first multi-taxon survey revealed a considerable biological richness in the WJC. In all, 363 wild-growing vascular plant, 72 lichen and 26 bryophyte taxa were recorded. The sampling also yielded 34 bird and 5 bat species as well as 39 ground beetle, 5 harvestman and 64 spider species. Some species are new records for Berlin.

Keywords

bats, Berlin, birds, bryophytes carabids, harvestmen, graveyard, lichens, plants, spiders, urban cemetery

Introduction

Cities can harbor a considerable number of plant and animal species (McKinney 2008, Shwartz et al. 2014). While there is a great deal of information on the biological richness of urban forest remnants and parks (e.g. Croci et al. 2008, Nielsen et al. 2014), cemeteries are clearly understudied, although this land-use type is ubiquitous in cities all over the world. Cemeteries are important components of the urban green infrastructure, simply because of their number and the area they cover. Berlin, for example, has 220 cemeteries within its limits, with a total area of about 1,125 hectares (SenStadtUm 2014).

A few studies on plants and animals, summarized in textbooks by Klausnitzer 1993 and Sukopp 1990 illustrate that cemeteries within a large city may play an important role for urban biodiversity due to their size, habitat heterogeneity and habitat continuity. Yet similarly to biodiversity studies on urban parks in general (Nielsen et al. 2014), earlier studies on the flora or fauna of cemeteries in Berlin have focused on single species groups and rarely comprise flora and fauna.

The present paper provides the first comprehensive inventory of a large urban cemetery in Berlin, the Weißensee Jewish cemetery (WJC), which is also one of the largest Jewish cemeteries (if not the largest) in Europe (Rütenik et al. 2013). The data set resulting from our multi-taxon approach includes information about the occurrences of several groups of plant taxa (vascular plants, bryophytes, lichens) and animal taxa (bats, birds, ground beetles, harvestmen, spiders). These data were recorded to support a World Heritage Initiative beginning in 2006, in particular to illustrate habitat functions of WJC that may back future approaches in linking biodiversity conservation and heritage preservation (Kowarik et al. 2011, Rütenik et al. 2013).

Material and methods

Study site

The study was performed in Berlin, Germany, which has a population of 3.5 million people within an area of 892 km². The WJC is 39.2 ha and is situated in northeastern Berlin (central point: 52°32'40"N, 13°27'30"E). It was established in 1880 by the Jewish community and has about 116,000 graves (Rütenik et al. 2013). The design and plant use at WJC is similar to that of contemporary Christian cemeteries, with cemetery sections separated by tree-lined avenues (von der Lippe et al. 2011). The cemetery was never destroyed, but the numbers of burials and the intensity of management sharply declined at the end of the 1930s due to the Shoah (Rütenik et al. 2013). As a consequence, large parts of the WJC developed into woodland (Figs 1, 2). While only smaller parts of WJC, close to the entrance, were covered with frequently mowed lawns or with intensively managed ornamental plantings, major parts are dominated by trees. These woodlands are subject to different management intensities, ranging from regularly managed parts to unmanaged parts where wild woodlands were allowed to develop (Figs 1, 2). The main focus of management efforts is on uprooting wild tree saplings and shrubs. Vegetation structure and prevailing plant species are similar to other spontaneously grown woodlands in Central European cemeteries, with *Acer platanoides*, *A. pseudoplatanus* and *Fraxinus excelsior* as dominant tree species, and *Hedera helix*, *Dryopteris filix-mas* and *Impatiens parviflora* as abundant herb species (Passarge 1990). Features of the sepulchral architecture (types, materials, age), which shape many habitats for mosses, lichens and vascular plants, are extensively reported by Rütenik et al. 2013.

Sampling methods

We sampled different groups of plants and animals in a nested design on three spatial scales (Table 1): an area-wide recording of the entire cemetery for bats, birds and vascular plants; a sampling of selected cemetery sections ($n= 30$) and selected family graves for lichens and bryophytes; and a sampling of 10×10 m plots (one in each of 30 selected cemetery section) for vascular plants, carabid beetles, harvestmen and spiders.

Table 1.

Sampling methods and spatial scales of the multi-taxon survey in the Weißensee Jewish Cemetery, Berlin.

TAXON	AREA-WIDE	CEMETERY SECTIONS	PLOTS
BATS	9 month period (January to September 2013) using bat detectors, mist-netting (one night in July 2013, 4 mist nets)	-	-
BIRDS	12 sampling days from April to June 2013 following Südbeck et al. 2005	-	-
VASCULAR PLANTS	Repeated floristic inventories from April 2013 to October 2014	-	Vegetation inventories of 30 cemetery sections (10×10 m plots, April and May 2013) following Braun-Blanquet 1964

Lichens and bryophytes	-	Recorded in 30 cemetery sections and additionally on tombstones and other structures (e.g. walls, graves of honor); June to December 2013	-
Carabid beetles	-	-	Three pitfall traps (diameter 9 cm, depth 12 cm, filled with 4% formalin-detergent solution) per cemetery section (N = 30), April 24–June 24, 2013.
Harvestmen	-	-	see carabid beetles
Spiders	-	-	see carabid beetles

Identification methods & analyses

For the multi-taxon survey, field observations and samplings were done by five experts (Table 2). Ground-dwelling arthropods caught in the traps were identified by three experts in the laboratory.

Table 2.

Identification methods and experts of taxa sampled in the Weißensee Jewish Cemetery. Experts: AL = Andreas Lemke, AS = Axel Schönhofer, BS = Birgit Seitz, JS = Jens Scharon, KH = Karsten Hannig, TB = Theo Blick, TT = Tobias Teige, VO = Volker Otte

Taxon	Identification	Nomenclature	Experts
Bats	Dietz et al. 2007	Dietz et al. 2007	TT
Birds	Mullarney et al. 2011	Barthel and Helbig 2005	JS
Vascular plants	Jäger 2011	Buttler and Thieme 2015, Jäger 2011	BS, AL
Lichens and bryophytes	Nebel and Philippi 2005, Wirth et al. 2013	Nebel and Philippi 2005, Wirth et al. 2013	VO
Carabid beetles	Müller-Motzfeld 2006	Müller-Motzfeld 2006	KH
Harvestmen	Martens 1978	Martens 1978	AS
Spiders	Nentwig et al. 2015, Roberts 1987, Roberts 1998	WSC 2015	TB

Based on the observed species richness of ground-dwelling arthropods we calculated the Chao 1 estimator using the R software environment (version 3.0.1, RCoreTeam 2013).

Data resources

In all, 363 wild-growing vascular plant taxa were recorded. Of these, 140 grew within the sample plots (Table 3). Twenty-five plant taxa were of conservation concern (Fig. 3): 15

species were threatened, 5 species were near-threatened and 3 species, *Centaurium erythraea*, *Epipactis helleborine* and *Helichrysum arenarium*, were protected by law. Two species, *Potentilla sterilis* and *Urtica subinermis* were newly recorded for Berlin. *Urtica subinermis* was formerly assessed as a subspecies of *Urtica dioica* (Buttler and Hand 2007). The sampling of 30 cemetery sections revealed 72 taxa of lichens and 27 taxa of bryophytes (Tables 4, 5, Fig. 5). Two bryophytes and five lichens were threatened, one lichen species (*Hyperphyscia adglutinata*) was considered to be extinct in Berlin and one (*Aloxyria ochrocheila*) was newly recorded for Berlin and is very rare in northeastern Germany.

Table 3.

Wild-growing vascular plants recorded during the area-wide and plot-based recording. Frequency was only assessed for species sampled in plots (100% = 30 plots). Explanations: Red List (Prasse et al. 2001): § = protected by law, * = not threatened, V = near threatened, 3 = vulnerable, 2 = endangered, 1 = critically endangered, ? = data deficient, nr = new record for Berlin; N = species non-native to Berlin, (N) = species native to Berlin with populations descending exclusively from cultivation (Seitz et al. 2012).

During the plot-based sampling, 39 carabid beetle (793 individuals), 5 harvestmen (2247 individuals) and 64 spider (4559 individuals) species were caught (Table 8, Fig. 6). Among the ground-dwelling arthropods, two species were threatened and one, *Agonum gracilipes* (Carabidae), was considered to be extinct. *Nemastoma dentigerum* (Opiliones) and *Porrhomma microcavense* (Araneae) are new records for Berlin.

Table 8.

Figure 6.

European spider of the year 2015: *Anyphaena accentuata*. Photo: C. Komposch.

All species were native to Berlin except 118 species of vascular plants. The differentiation of natives and neophytes (post-1492 introductions) followed Seitz et al. 2012. Native species and pre-1492 introductions (i.e., archeophytes) were not differentiated.

Conclusion

Our dataset illustrates that old cemeteries within a large city can harbor a considerable biological richness and therefore may play an important role for urban biodiversity conservation. Our results add evidence to findings from urban cemeteries and urban parks with large woodland patches (e.g., Graf 1986, Fudali 2001, Kocian et al. 2003, Croci et al. 2008, Gao et al. 2013, Philpott et al. 2014), but, for the first time, from a multi-taxon perspective. Our sampling approaches yield an overview over species assemblages of a range of groups of taxa. Yet due to limited sampling pressure, the inventories of the ground-dwelling arthropods are likely incomplete. Accordingly, species richness estimators show that a higher diversity can be expected, for example by applying other sampling techniques and catching for a larger timespan. However, although a two month sampling period is rather short, recent studies have shown that this period is sufficient to yield reliable data (Pearce et al. 2004, Vergnes et al. 2014). Pitfall traps only catch surface running species while species occurring in higher vegetation strata are rarely caught (Jimenez-Valverde and Lobo 2005). So further hand-sampling or sweep-netting studies should add a number of web building species to the species inventory presented. Since conservation and environmental planning is often restricted to few taxa (Gobbi et al. 2012), our dataset is especially important as it is the first which provides evidence that urban cemeteries could have an overall positive habitat function for many groups of taxa. Our data is thus a valuable snapshot that illustrates the relevance of this large urban cemetery for biodiversity conservation in Berlin. This is important information for urban planners, conservationists and gardeners that, however, needs being substantiated by further studies

on the role of cultural parameters (e.g., management intensity) and environmental parameters (e.g., vegetation structure) in modulating biodiversity functions for different groups of taxa.

Acknowledgements

We thank M. Eis, S. Gerst, A. Hiller, F. Swolana and S. Pohl for supporting field work and Mauro Gobbi and Ivan Tuf for helpful comments on a previous version. The work was funded by Deutsche Bundesstiftung Umwelt (DBU project AZ 29773 “Integration von Naturschutzz Zielen bei der Bewahrung und Entwicklung des Jüdischen Friedhofs Berlin-Weißensee”) and kindly supported by the Jewish Community of Berlin.
