Abstract

Background

We present a checklist of annelids from recent United Kingdom Seabed Resources (UKSR) expeditions (Abyssal Baseline - ABYSSLINE project) to the eastern abyssal Pacific Clarion-Clipperton Zone (CCZ) polymetallic nodule fields, based on DNA species delimitation, including imagery of voucher specimens, Darwin Core (DwC) data and links to vouchered specimen material and new GenBank sequence records. This paper includes genetic and imagery data for 129 species of annelids from 339 records and is restricted to

material that is, in general, in too poor a condition to describe formally at this time, but likely contains many species new to science. We make these data available both to aid future taxonomic studies in the CCZ that will be able to link back to these genetic data and specimens and to better underpin ongoing ecological studies of potential deep-sea mining impacts using the principles of FAIR (Findable, Accessible, Interoperable, Reusable) data and specimens that will be available for all.

New information

We include genetic, imagery and all associated metadata in Darwin Core format for 129 species of annelids from the Clarion-Clipperton Zone, eastern abyssal Pacific, with 339 records.

Keywords

taxonomy, DNA barcoding, biodiversity, conservation, deep-sea mining, abyssal Pacific, environmental impact

Introduction

We present a checklist of annelid fauna from recent UKSR expeditions (ABYSSLINE project) to the CCZ the equatorial abyssal Pacific, based on DNA species delimitation, including imagery of voucher specimens, Darwin Core data (DwC) and links to vouchered specimen material and new GenBank sequence records. This is a region undergoing significant exploration for mineral resources in the form of polymetallic nodules at the seafloor (Hein et al. 2013) and, as such, future environmental monitoring of these areas will require access to information on the biodiversity of animals at the seafloor, in particular based on sound taxonomic sources (Glover et al. 2018, Rabone et al. 2023a, Rabone et al. 2023b).

Surveying of this region over the past 20 years resulted in a large collection of often very small, morphologically sub-optimally preserved and difficult to identify annelids, despite the best efforts at collecting animals directly from samples at sea using cold-chain protocols (Glover et al. 2015). Typically, the specimens can be identified to family or genus at best. Although good quality DNA sequences were obtained in most cases, there are few genetic matches to sequences available on public databases (Suppl. material 1), most being from other studies in the CCZ (Janssen et al. 2015, Janssen et al. 2019, Bonifácio and Menot 2019, Bonifacio et al. 2020, Bonifácio et al. 2021) or abyssal Atlantic (Boggemann 2009, Boggemann 2016). Based on detailed taxonomic studies that also incorporated molecular data (e.g. Wiklund et al. 2019, Bonifácio and Menot 2019, Neal et al. 2022a, Neal et al. 2022b, Bonifácio et al. 2021), over 80% of the CCZ-collected annelids are likely new to science (Rabone et al. 2023b). To date, publications from the areas targeted in this study have yielded 60 annelid species from 327 specimen records, of

which only 18 species have been formalised as new (Wiklund et al. 2019, Drennan et al. 2021, Neal et al. 2022a, Neal et al. 2022b). However, we are left with a problem in that many specimens are in sub-optimal morphological condition and unable, therefore, to be formally described. Therefore, in order to ensure that this material is accessible and useful as more comparative material is recovered in future surveys and that the DNA sequences obtained are linked transparently to openly-available molecular tissue/DNA and specimen vouchers, we are making these data and materials available in the form of this checklist paper. This has two major advantages: firstly, it enables future taxonomic work with better materials to use and to link to these data and potentially describe more of these specimens; secondly, it provides openly available data on the actual species hypotheses used to support ecological papers describing the biodiversity of the CCZ (Rabone et al. 2023b), which clearly suffer from a lack of quality control in the specimen identifications available, as has been recently acknowledged (Bianchi and Gonçalves 2021, Washburn et al. 2021). This checklist also provides supporting data to Stewart et al. (2023) describing the biodiversity and connectivity of annelids across the entire eastern CCZ region.

This paper includes a checklist of 129 annelid species, with 339 records from 18 polychaete families and four species of Sipuncula. Excluded from this study are several annelid families which are common in the CCZ, but are either ones that have already been studied (Wiklund et al. 2019, Drennan et al. 2021, Neal et al. 2022a, Neal et al. 2022b) or are currently in preparation in separate detailed taxonomic papers (e.g. order Phyllodocida and families Acrocirridae and Serpulidae).

Materials and methods

Sampling

The first UKSR ABYSSLINE cruise (AB01), sampling the UK-1 exploration contract area, took place in October 2013 aboard the RV *Melville* and the second cruise (AB02), sampling the UK-1 and OMS-1 (Ocean Minerals Singapore) exploration contract areas and one Area of Particular Environmental Interest (APEI), APEI-6, took place in February–March 2015 onboard RV *Thomas G. Thompson*. Sampling locations are as indicated in Fig. 1.

A comprehensive description of our methods is provided in Glover et al. (2015). In summary, deep-sea benthic specimens from the targeted CCZ areas were collected using a range of oceanographic sampling gear including box core, epibenthic sledge (EBS), ROV and multiple core. Geographic data from sampling activities were recorded on a central GIS database. Live-sorting of specimen samples was carried out aboard both vessels in a ‘cold-chain’ pipeline, in which material was constantly maintained in chilled, filtered seawater held at 2–4°C. Specimens were preliminarily identified at sea and imaged live using stereomicroscopes with attached digital cameras. Only annelid specimens with a visible head end were counted and included in taxonomic and biodiversity analyses. The specimens were then stored in individual microtube vials containing an aqueous solution of 80% non-denatured ethanol, numbered and barcoded into a database and kept chilled until return to the Natural History Museum (NHM), London, UK.

Laboratory Work

In the laboratory, specimens were re-examined using stereomicroscopes, identified to the best possible taxonomic level and a small tissue sample was taken for DNA extraction. In most of the specimens in this study, the material was too poor or degraded to make species-level identifications.

Extraction of DNA was done with DNeasy Blood and Tissue Kit (Qiagen) using a Hamilton Microlab STAR Robotic Workstation. About 450 bp of 16S and 650 bp of cytochrome c oxidase subunit I (COI) were amplified using primers listed in Table 2. PCR mixtures contained 1 µl of each primer (10 µM), 2 µl template DNA and 21 µl of Red Taq DNA Polymerase 1.1X MasterMix (VWR) in a mixture of total 25 µl. The PCR amplification profile consisted of initial denaturation at 95°C for 5 min, 35 cycles of denaturation at 94°C for 45 s, annealing at 55°C for 45 s, extension at 72°C for 2 min and a final extension at 72°C for 10 min. PCR products were purified using Millipore Multiscreen 96-well PCR Purification System and sequencing was performed on an ABI 3730XL DNA Analyser (Applied Biosystems) at NHM Sequencing Facility, using the same primers as in the PCR reactions (Table 2). Overlapping sequence fragments were merged into consensus sequences using Geneious (Kearse et al. 2012) and aligned using MAFFT (Katoh 2002) for 16S and MUSCLE (Edgar 2004) for COI.

Species delimitation and taxonomic assignments

Future studies of biogeographic and bathymetric ranges, gene-flow, extinction risks, natural history, reproductive ecology, functional ecology and geochemical interactions of CCZ species are dependent on accurate taxonomic identifications. Our more recent taxonomic studies (e.g. Glover et al. (2016), Dahlgren et al. (2016), Wiklund et al. (2017), Wiklund et al. (2019), Drennan et al. (2021), Neal et al. (2022a), Neal et al. (2022b)), applied an integrative DNA taxonomy approach, with species delimitation principally based on a

phylogenetic species concept, *sensu* Donoghue (1985) coupled with morphological interpretations. However, in this broader study of all of the annelids, including many poorly-preserved or fragmented individuals, we have relied more heavily on genetic data.

Taxonomic assignments and nomenclature

Almost all species discriminated by the analyses could be identified to family level from morphology and this was cross-checked with the genetic data through a BLAST search. Given the poor preservation of morphology and the goals of this paper to make specimen and genetic data rapidly available for any future studies, we did not attempt to force species into genera in most instances and used an open nomenclature whereby the species are named with the best taxonomic level and a species epithet that refers to the best voucher specimen of that species. For example, Pilargidae sp. (NHM_015) is the informal species name for the species that is represented by two specimens, specimen NHM_015 being the better representative (an informal type specimen). This avoids confusion with the use of sp. A, B, C etc. where informal and confusing synonyms can easily arise.

Species were delimited, based on well-supported clades recovered from phylogenetic trees estimated separately for 16S and COI sequences. Best nucleotide substitution models for each alignment (i.e. 16S and COI) and best-fit partitions were inferred using PartitionFinder 2.0 (Lanfear et al. 2017), utilising a greedy clustering algorithm (Lanfear et al. 2012) and PhyML v.3 (Guindon et al. 2010). Phylogenetic trees were estimated using Bayesian Inference in BEAST v.2.6.2 (Bouckaert et al. 2019) under a Yule speciation model, uncorrelated relaxed clock, GTR+I+G substitution model for each partition of COI (codon positions 1, 2 and 3) and for 16S and a chain length of 100 M, sampling every 10,000. The MCMC runs were inspected convergence in Tracer v.1.7.1. The first 50 M states were discarded as burn-in and a consensus median heights tree was generated from the remaining posterior trees. Trees were visualised using FigTree v.1.4.4 and species clusters were mostly defined from very similar sequences recovered in monophyletic clades with a posterior probability of 1.

Data Handling

The field and laboratory work created a series of databases and sample sets that are integrated into a data-management pipeline. This includes the transfer and management of data and samples between a central collections database, a molecular collections database and external repositories (GenBank, WoRMS, OBIS, GBIF, GGBN, ZooBank) through DwC archives. This provides a robust data framework to support DNA taxonomy, in which openly available data and voucher material is key to quality data standards. All DwC data present in the taxon treatments of the checklist herein are also provided as a supplementary data file to allow for ease of usage (Suppl. material 2). A further elaboration of the data pipeline is published in Glover et al. (2015).

Diagnosis: Damaged specimen (Fig. 44) consistent with placement within family Glyceridae, based on morphology and DNA.

Figure 44. [doi](#)

Glyceridae sp. (NHM_207), anterior end of live specimen NHM_359 with extended proboscis.

Distribution: Eastern Clarion-Clipperton Zone, central Pacific Ocean.

Glyceridae sp. (NHM_1242)

Diagnosis: Damaged specimens (Fig. 86) consistent with placement within family Polynoidae, based on morphology and DNA. Genetically matches with *Bathyfauvelia* sp. 225 as identified in Bonifácio et al. (2021).

Discussion

Species checklists are critical tools in biodiversity and conservation that can be used to underpin our understanding of biological change and appropriate policy measures (Reyserhove et al. 2020, Rabone et al. 2023b). However, checklists are of limited value if the data are not freely available. Therefore, the emphasis of this publication is on open data following the FAIR principles (Wilkinson et al. 2016). Recent years have seen an increased emphasis on FAIR data, resulting in a resurgence in the public availability of checklists (Rabone et al. 2023a, Rabone et al. 2023b), also exemplified by the success of the [World Register of Marine Species](#).

More often than not, ecological papers describing biodiversity do not include a list of all the species and specimens used to make the broader ecological inferences and even more rarely make the specimens and all associated metadata available in a FAIR way (Bianchi and Gonçalves 2021). In this study, we have made a significant and time-consuming attempt to do this, in a region of the global oceans where critical policy decisions are being

made that could impact the way humanity obtains its resources and manages its environment in a sustainable way.

Acknowledgements

We thank the masters, crew and technical staff on the RV "Melville", RV "Thomas G Thompson" and M/V "Pacific Constructor" for their outstanding support. This research was supported by funding from UK Seabed Resources Ltd and Natural Environment Research Council grant 'SMARTEX - Seabed Mining and Resilience to Experimental Impact' grant NE/T002913/1. We particularly acknowledge the continued support of UK Seabed Resources over the last eight years for funding the fundamental taxonomic studies necessary to provide information for the regulation of potential industrial activity. We acknowledge the continued support from the NHMUK Consultancy team (Harry Rousham, Robyn Fryer, Kate Rowland) and Jackie Mackenzie-Dodds, manager of the NHM Molecular Collection facility (MCf). We received help sorting and sieving samples at sea from Magdalena Georgieva and Madeleine Brasier and the entire ABYSSLINE science team in successful deep-sea coring operations.

Author contributions

Helena Wiklund, Adrian Glover, Thomas Dahlgren and Lenka Neal conceived and project-managed the study. Lenka Neal wrote, organised and arranged the figures and systematics sections. Muriel Rabone created the DwC database of the taxon treatments for the checklist. Eva Stewart carried out the barcode gap analysis and produced the figures. Regan Drennan contributed to the systematics section. Emma Sherlock contributed the NHM accessioning work including final curation of specimens. Corie Boolukos and Lucas King assisted with the curation of specimens both for the NHM main collection and for the molecular archive in the Molecular Collection facility and assisted with data handling. Craig Smith led all the ABYSSLINE research cruises. All authors contributed significantly to the production of the checklist and the manuscript and including revisions of drafts and approved the final manuscript.
